# In this talk ...

1. Motivation
2. Landslide data acquisition
3. Landslide susceptibility modelling
  - *From regional to tree scale*
4. Decision support for land management
5. Key messages

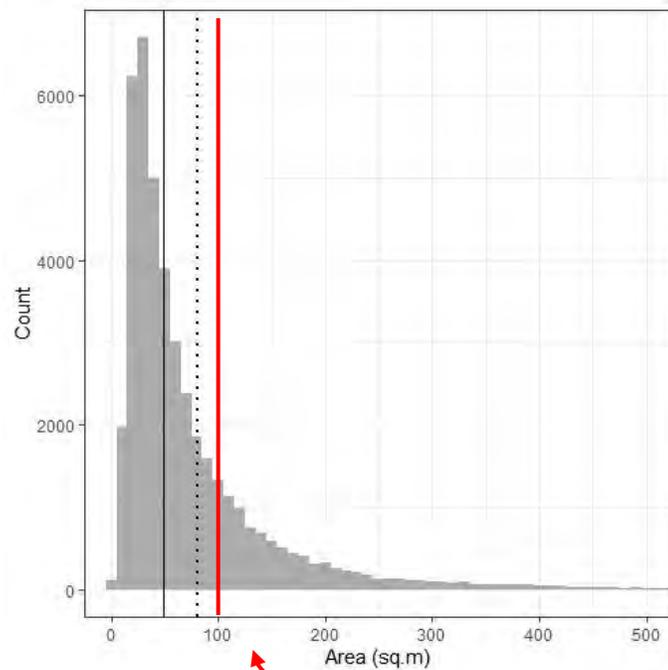

# From remote sensing to decision support

- **WHY:** To support the design and implementation of cost-effective, targeted erosion control measures to meet national water quality targets.
- **HOW:** Acquire data and develop models to:
  - Quantify links between erosion sources and sediment-related water quality
  - Determine the performance of erosion control measures across multiple spatial scales

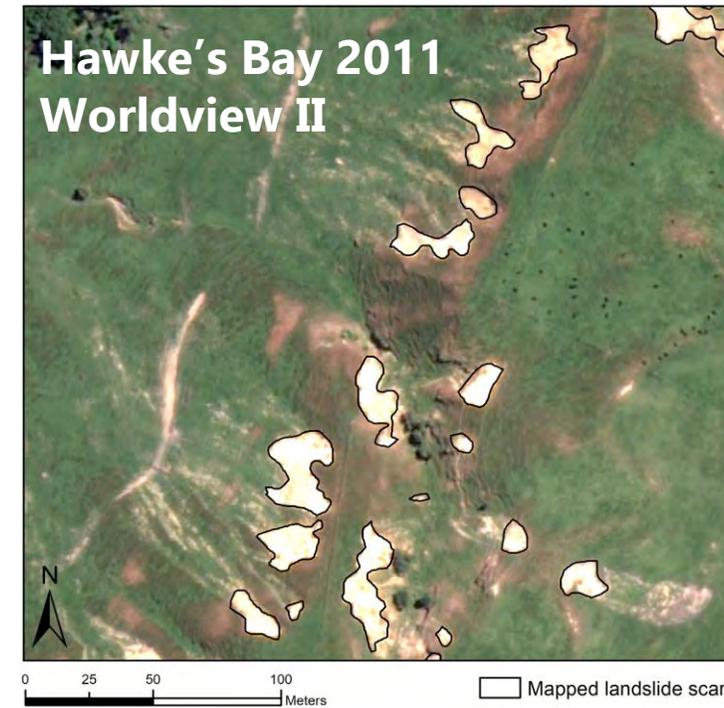

# Shallow landslide mapping

- Scale of imagery determined by geomorphic process

Typical distribution of scar size in soft rock hill country

Sentinel II – 10 m GSD  
1 pixel = 100 m<sup>2</sup>

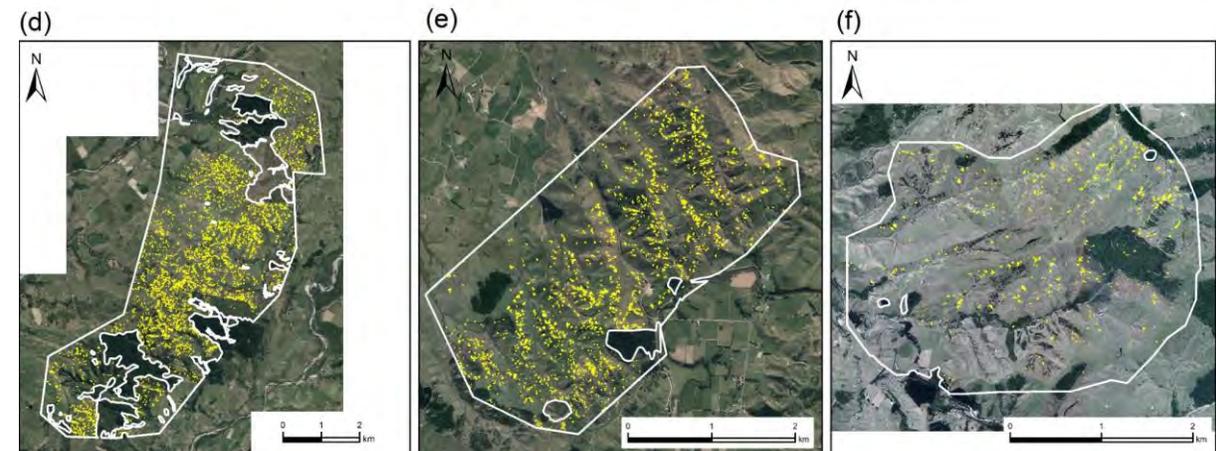

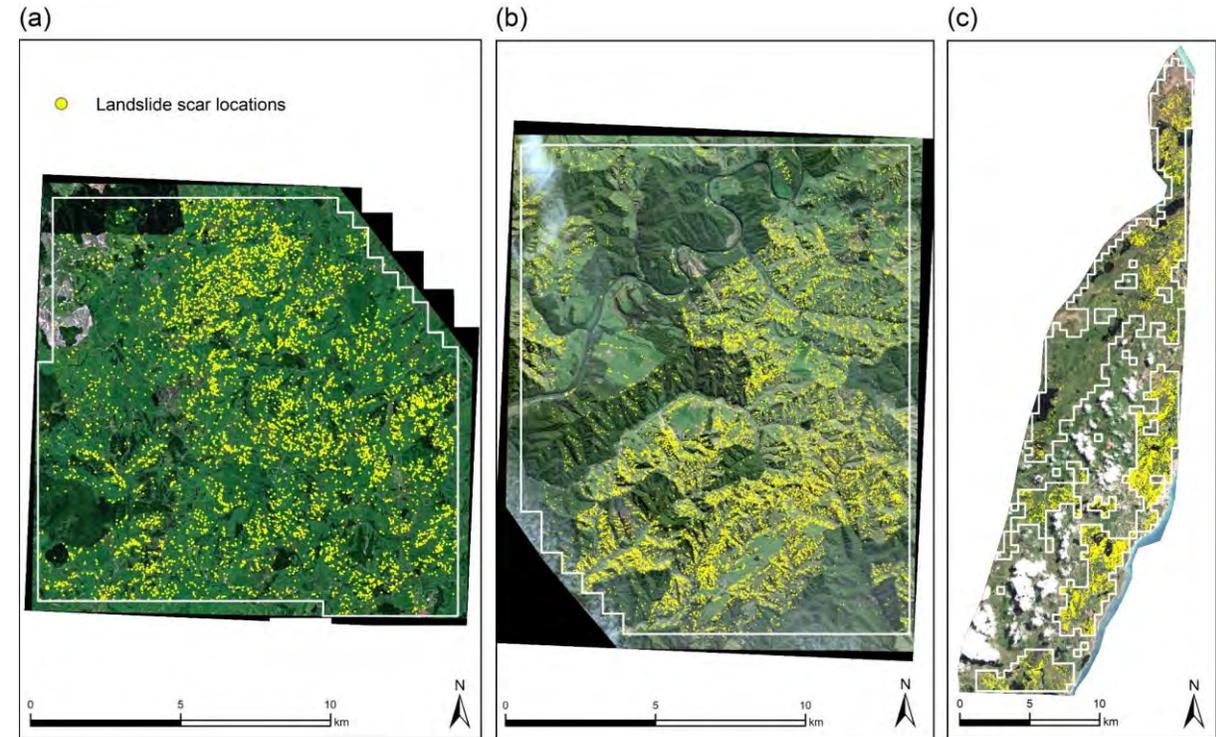

WV2 – 0.5 m GSD  
1 pixel = 0.25 m<sup>2</sup>

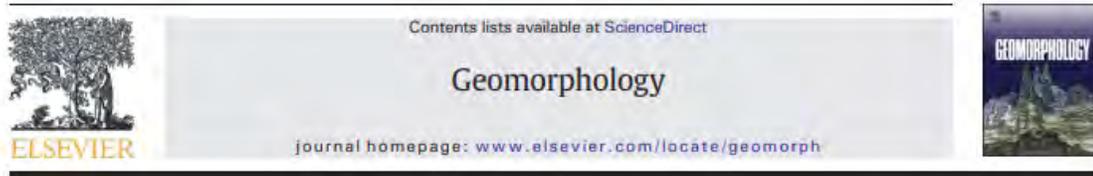

# Landslide mapping

- Build landslide inventories by mapping from high-resolution imagery (< 1 m)
- Compare data sources:
  - a) manual vs. semi-automated mapping
  - b) event vs. historic records

Geomorphology 381 (2021) 107660

Comparing methods of landslide data acquisition and susceptibility modelling: Examples from New Zealand

Hugh G. Smith \*, Raphael Spiekermann, Harley Betts, Andrew J. Neverman

Manaaki Whenua – Landcare Research, Palmerston North, New Zealand

# Object-based image analysis (OBIA) for rapid landslide mapping

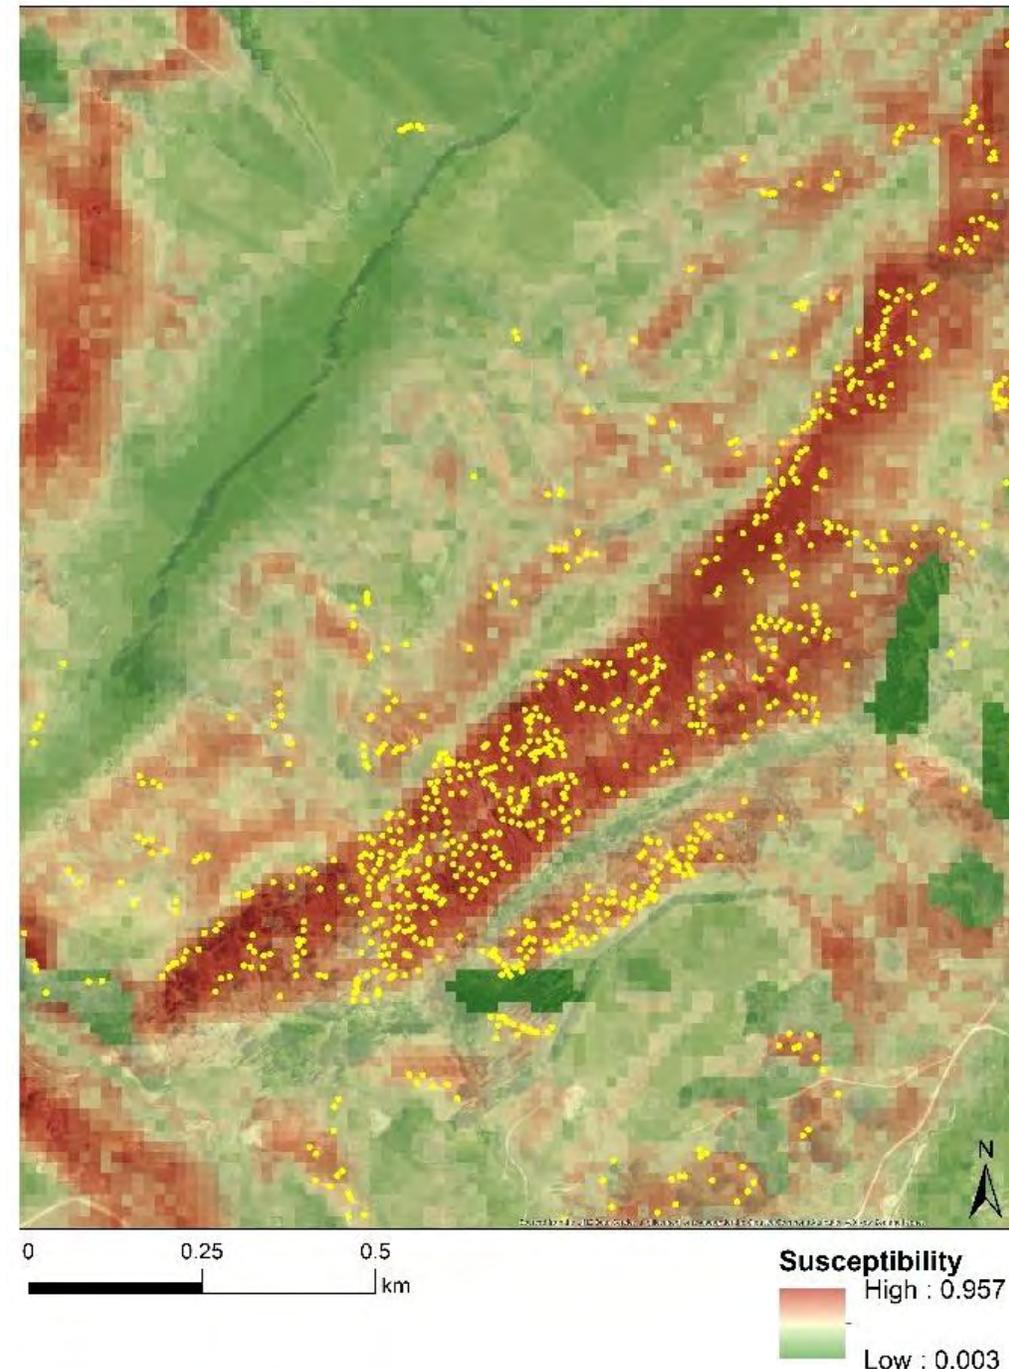

# Landslide susceptibility

## Shallow landslide susceptibility

- The likelihood of future landslide occurrence for a given areal unit given local environmental conditions.
- Focus on rainfall-triggered shallow landslides.

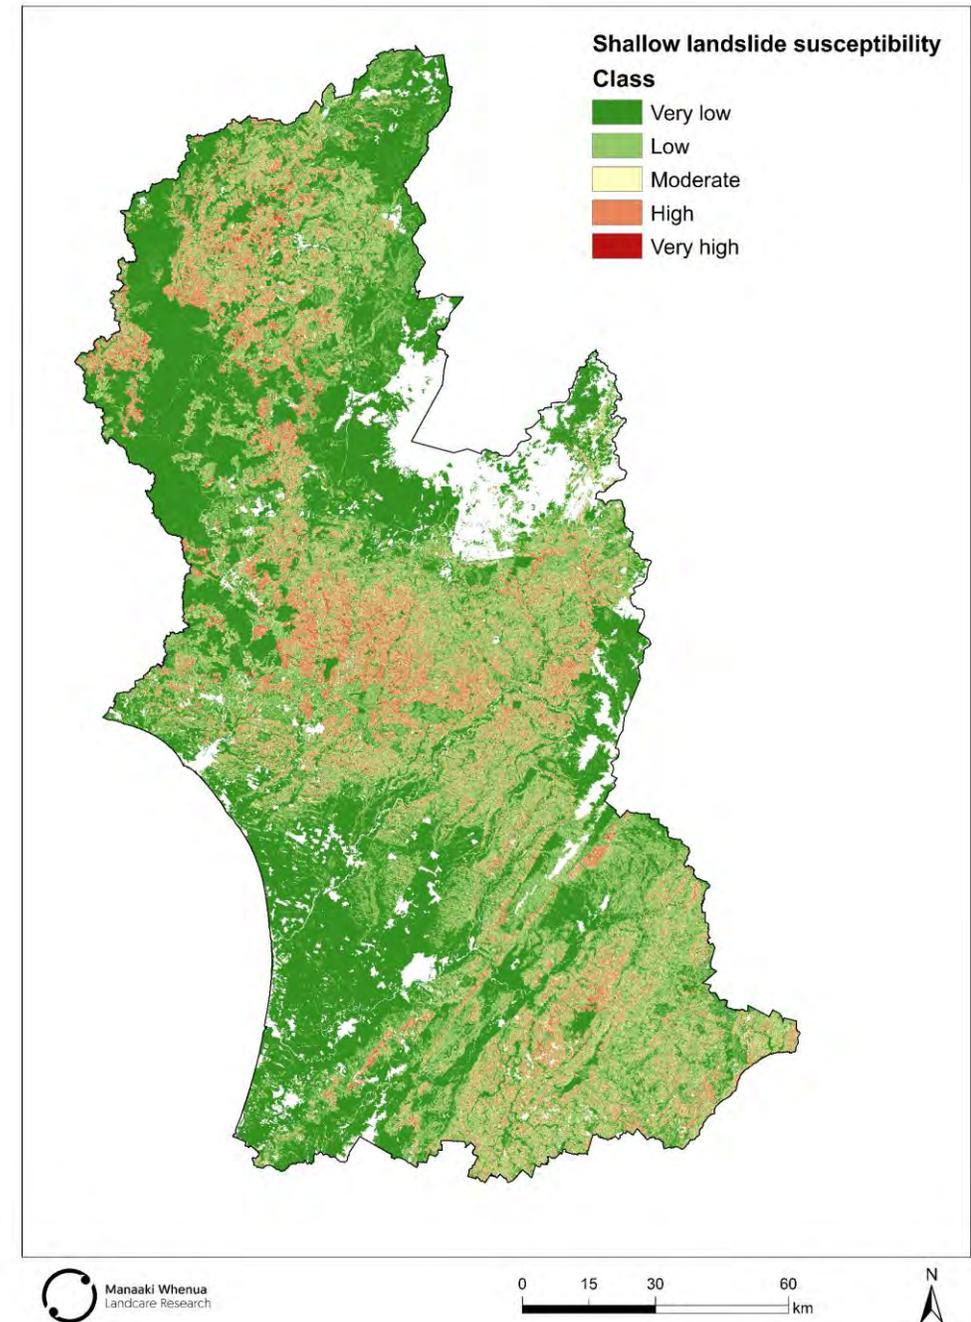

## Method

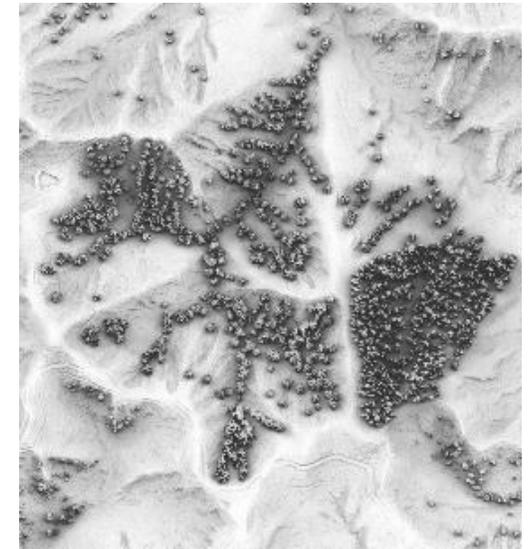

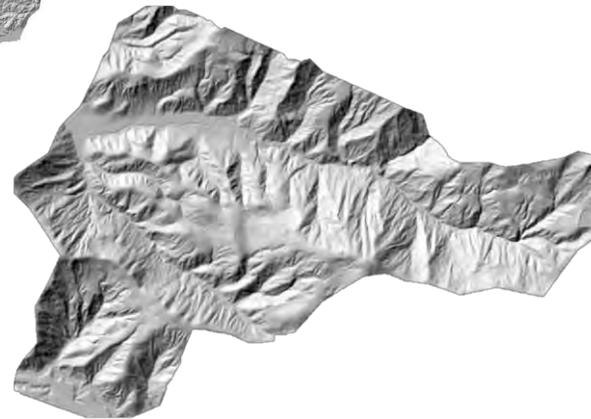

- Extract spatial data for **landslide** and **non-landslide** locations (e.g. slope, aspect, land cover).
- Train model to predict likelihood of landslide occurrence for each grid cell.
- Model output is a probability (0 – 1) that can be given a class (e.g. 'high').
- Model predicts **where** and not **when** landslides may occur.

# National / regional scale

- MWLR has developed models to predict spatial patterns in susceptibility to rainfall-initiated shallow landslides
- Draws on database of >100,000 shallow landslides

**NATIONAL/REGIONAL:** 15m national DEM / 5m LiDAR DEM derivatives, LCDB

**CATCHMENT/FARM:** 5m LiDAR DEM derivatives, LCDB

**FARM/TREE:** 1m LiDAR DEM derivatives, individual trees

## Different data <> Different questions

# Key Messages:

- Remote sensing techniques facilitate rapid acquisition of large quantities of landslide data for modelling.
- Statistical landslide susceptibility modelling provides a data-driven approach to better target erosion control from region to paddock scale.
- LiDAR enables new higher-resolution data collection and analysis, including individual trees.
- Mitigation can be targeted to sediment source locations with the connectivity model.
- Scenario modelling indicates targeted mitigation results in a 10-fold increase in cost-effectiveness of measures.

**This research was supported by the MBIE research program  
“Smarter Targeting of Erosion Control (STEC)”**
